Forest Mensuration and Statistics Branch
STATE FOREST RESEARCH INSTITUTE
JABALPUR (M.P.)
2016

FOREWORD

Volume tables for the scientific management of forests are most essential. Although volume tables for sal have earlier been prepared but, of late, it has been felt that at times and at varying places there is larger gap between estimated yield and actual yield. This gap invites audit objection for absolutely no physical loss. To minimize this problem volume tables of *Shorea robusta* (Sal) have been revised by this institute for Anuppur, Balaghat, Dindori, Mandla, North Shahdol, Sidhi and South Shahdol forest divisions.

I hope that these revised volume tables for sal will be useful to forest officers in the management of forests.

Dr. G. Krishnamurthy, IFS

Director

State Forest Research Institute, Jabalpur

Jabalpur, 2016

ACKNOWLEDGEMENT

The compilation of volume tables is a result of long term tedious work. I am thankful to the former director Dr. P. K. Shukla, PCCF, Retd. for his guidance and encouragement in the preparation of these volume tables. I also thank former director, Dr. Ramprakash APCCF, Retd. for his support in completing this work. I am grateful to former director, late Shri Vijay Bahadur, APCCF, Retd. for giving facility for completion of this work.

I thank to former branch head Shri A. K. Hazari, ACF, Retd. for his continuous effort to complete this work. I thank the associates Shri Shishupal Singh Mehta, Shri Mahesh Prasad Soni, Shri Mayank Makrand Verma for giving necessary assistance in data collection and data compilation. Mohammd Asif Mansoori and Sakshi Seth also deserve thanks for impeccable computer works.

I thank branch head Shri S. K. Jain, ACF for his guidance, Lastly I thank Dr. G. Krishnamurthy, Director, State Forest Research Institute for giving his precious time and support to go through the compilation and suggesting necessary corrections. It is only he, who motivated the present compilation work to make presentable.

Jabalpur, 2016

VOLUME TABLES OF *Shorea robusta* (SAL) FOR VARIOUS DIVISIONS OF MADHYA PRADESH

1. Introduction

Sal (*Shorea robusta*) is most important timber species in Madhya Pradesh. It is a large evergreen tree belonging to the family Dipterocarpaceae. Sal forests of Madhya Pradesh are ecologically very important as they mark the termination of the great Sal zone of the Central Indian Peninsula. Sal forests are located in the eastern part of the state while teak forests are localised in the western part. In between, there is a transition belt of mixed miscellaneous forests. There are also areas where Teak and Sal both species occur naturally mixed together forming unique ecosystem. Sal forests occupy an area of 7244 km², which is about 7.6 % of the total forest area of the state. The Sal forests are confined to the eastern part of the state in the districts Rewa, Sidhi, Umaria, Anuppur and southwards in districts Balaghat, Mandla, Dindori, and Jabalpur and occupy all ranges of Maikal and the highlands of Balaghat. Sal forests are also distributed in and around Pachmarhi in Hoshangabad and Chhindwara districts.

In the meeting with the Additional Principal Chief Conservator of Forests (Production) Madhya Pradesh, held on 2.8.2004, it was decided that the form factors of teak species be prepared for various production circles and divisions. For this purpose, the data to be used was that available from the registers of production coupes and that there would not be any necessity for taking measurements of trees separately. The data required for the analysis will be provided to the State Forest Research Institute (SFRI), Jabalpur, by Additional Principal Chief Conservator of Forests (Production). The volume tables will be prepared by SFRI, for various girths and site qualities.

To prepare the local volume tables for different site qualities, the local volume equations based upon only one parameter, i.e. girth at breast height (GBH), has been taken into consideration. These volume tables based on one independent variable i.e. dbh or gbh, are derived from the measurements of trees growing in a restricted geographical area or locality, or more or less uniform crop. These are, therefore, applicable to such restricted range of locality or geographical areas, only where the assumption that the trees of the same diameter will have the same height, holds good.

2. Methodology

The different steps for calculating girth class-wise volume table for various divisions are being described as under.

2.1. Source of data

The data of Sal species for different divisions for different site qualities were provided by the concerned

divisions. The analysis for volume calculations of timber and fuel content for sound, half sound and unsound trees was carried out on the available data.

2.2 Regression equations used:

a) For estimation of timber content

The following types of regression equations were tried to obtain timber content in sound, half sound and unsound trees. These are local volume equations (Volume equation for forest of India, Nepal and Bhutan. Forest Survey of India, 1996) with only one independent variable, i.e. girth at breast height (G).

- (i) $V = a + bG^2$
- (ii) $V = a + bG + cG^2$
- (iii) $V = a + bG + cG^2 + dG^3$
- (iv) $V = a + b\sqrt{G} + cG^2$
- (v) $\sqrt{V} = a + bG$
- (vi) $\sqrt{V} = a + bG + c\sqrt{G}$
- (vii) $\log_e V = a + b\log_e G$

Where

V = Under-bark volume (cmt) of timber

G = Over-bark girth of standing trees at breast height (cm)

And **a**, **b**, **c** and **d** are statistical constants.

The best-fit regression equation was used to estimate the volume.

b) For estimation of fuel content

The following curve estimation models were tried for estimation of fuel content in sound, half sound and unsound trees on the basis of the curve estimation models given in SPSS software.

- (i) $F = a + bG$ (Linear)
- (ii) $F = a + b\log_e G$ (Logarithmic)
- (iii) $F = a + b/G$ (Inverse)
- (iv) $F = a + bG + cG^2$ (Quadratic)
- (v) $F = a + bG + cG^2 + dG^3$ (Cubic)
- (vi) $F = \text{EXP}(a + b/G)$ (S-curve)
- (vii) $F = \text{EXP}(a + bG)$ (Growth)

Where

V = Under-bark volume (cmt) of timber

G = Over-bark girth of standing trees at breast height (cm)

And **a**, **b**, **c** and **d** are statistical constants.

The best-fit regression equation was used to estimate the fuel content.

As per the instructions received from the APCCF (Production), mean value for girth classes with class interval of 10cms have been worked out and given in Table 1 to 7(d) . However, it may be noted that the error is likely to increase if these mean values are used instead of the exact girths of the trees. The total volume for a coupe will be correctly calculated only when all the girths are uniformly distributed over the whole girth-class, otherwise with skewed distribution of girths of individual trees in a girth-class, we are likely to underestimate or overestimate the volume. Estimated timber is liable to fall within the range of $\pm 5\%$ error using these tables. Estimated fuel content is liable to fall within the range of $\pm 10\%$ error using these tables.

3. Results and discussion

1. To estimate timber volume of sound, half sound and unsound trees, it was observed that most of the site qualities follow the same local volume equation $V = a + bG^2$ where **V** is the Under-bark volume (cmt) of timber, **G** = Over-bark girth of standing trees at breast height (cm) and **a** and **b** are constants. Therefore, only equation $V = a + bG^2$ was tried to estimate timber volume with the least possible error. While comparing the volume versus girth curves for various site qualities it was found, in some cases that lower site quality shows higher volume content than higher site quality for the same girth. This does not reflect the natural trend of volume variation with site-quality. This type of unnatural behaviour may be due to many reasons such as human error in the assessment of tree condition, mistakes in volume calculation, mixing data of full-sized trees and pollards and erroneous assessment of site -quality. During estimation of timber volume for sound timber, the efforts were made to minimize the error in total estimated volume. However, there still remains some error that has already been described in division wise report. The possible reasons for this difference are listed as below:

- i. The data, from statistical analysis point of view, for many girth classes are insufficient to establish significant correlation between volume and girth for that particular girth class.
- ii. The observed volume content in the field shows significant variations for the same girth and the same site quality of a tree. These variations may occur due to human errors, e.g. measurement error, writing error and volume estimating error etc. in the field.
- iii. In some cases, it was also observed that the trees of higher girth show lesser timber volume content as compared to the timber volume of trees of lower girth within the same site quality, which may be possible due to faulty classification of the condition of the tree. In nature, sometimes it is observed that

the hollowness starts to develop within the tree, as it grows older. If there is hollowness within the trunk of the tree but it appears sound from outside, then its status is liable to wrong classification.

- iv. The actual volume of a tree depends upon the girth, height and the tapering of the tree. But in the present case, the volume estimation is based only upon a single parameter, i.e. girth.
2. As per the instructions received from the APCCF (Production), mean values for girth classes with class interval of 10cms have been worked out. However, it may be noted that the error is likely to increase if these mean values are used instead of the exact girths of the trees. The total volume for a coupe can be correctly calculated only when all the girths are uniformly distributed over the whole girth-class, otherwise with skewed distribution of girths of individual trees in a girth-class there is possibility of underestimation or overestimation in the volume.
